

Solution 1:

- (a) Prior distribution (assuming the same notation as in the lecture):

$$\mathbf{f} \sim \mathcal{N}(\mathbf{m}, \mathbf{K})$$

with $\mathbf{m} = m(\mathbf{x})$ and \mathbf{K} defined by the entries $K_{ij} = k(x_i, x_j)$. NB: Note the (in-)finite Gaussian property of a GP.

- (b) Note that the posterior distribution $\mathbf{f}|\mathbf{y}, \mathbf{x}$ in this case is different from the one of $\mathbf{f}_*|\mathbf{x}_*, \mathbf{x}, \mathbf{y}$ and also from the marginal distribution of $\mathbf{y} \sim \mathcal{N}(\mathbf{m}, \mathbf{K} + \sigma^2 \mathbf{I})$! We have:

$$\begin{aligned} p(\mathbf{f}|\mathbf{y}) &\propto p(\mathbf{y}|\mathbf{f}) \cdot p(\mathbf{f}) \\ &\propto \exp\left(-\frac{1}{2}(\mathbf{y} - \mathbf{f})^\top (\sigma^2 \mathbf{I})^{-1} (\mathbf{y} - \mathbf{f})\right) \cdot \exp\left(-\frac{1}{2}(\mathbf{f} - \mathbf{m})^\top \mathbf{K}^{-1} (\mathbf{f} - \mathbf{m})\right) \\ &\propto \exp\left(-\frac{1}{2}\left\{\mathbf{f}^\top \underbrace{((\sigma^2 \mathbf{I})^{-1} + \mathbf{K}^{-1})}_{=: \mathbf{K}_{post}^{-1}} \mathbf{f} - 2\mathbf{f}^\top \underbrace{((\sigma^2 \mathbf{I})^{-1} \mathbf{y} + \mathbf{K}^{-1} \mathbf{m})}_{=: \tilde{\mathbf{f}}}\right\}\right) \\ &\propto \exp\left(-\frac{1}{2}\left\{\mathbf{f}^\top \mathbf{K}_{post}^{-1} \mathbf{f} - 2\mathbf{f}^\top \tilde{\mathbf{f}}\right\}\right) \end{aligned} \quad (1)$$

by removing all constant factors that do not depend on \mathbf{f} as we only need to know the density up to a constant of proportionality. By extending the proportionality, we can get a quadratic form in \mathbf{f} :

$$\begin{aligned} p(\mathbf{f}|\mathbf{y}) &\propto \exp\left(-\frac{1}{2}\left\{\mathbf{f}^\top \mathbf{K}_{post}^{-1} \mathbf{f} - 2\mathbf{f}^\top \tilde{\mathbf{f}}\right\}\right) \\ &\propto \exp\left(-\frac{1}{2}\left\{\mathbf{f}^\top \mathbf{K}_{post}^{-1} \mathbf{f} - 2\mathbf{f}^\top \mathbf{K}_{post}^{-1} \underbrace{\mathbf{K}_{post} \tilde{\mathbf{f}}}_{:= \mathbf{f}_{post}}\right\}\right) \\ &\propto \exp\left(-\frac{1}{2}(\mathbf{f} - \mathbf{f}_{post})^\top \mathbf{K}_{post}^{-1} (\mathbf{f} - \mathbf{f}_{post})\right) \end{aligned} \quad (2)$$

which is the so-called *kernel* of a multivariate normal distribution $\mathcal{N}(\mathbf{f}_{post}, \mathbf{K}_{post})$, i.e., $\mathbf{f}|\mathbf{y} \sim \mathcal{N}(\mathbf{f}_{post}, \mathbf{K}_{post})$.

- (c) In order to get the posterior predictive distribution for a new sample x_* from the same data-generating process, we could derive

$$p(y_*|\mathbf{x}_*, \mathbf{y}, \mathbf{x}) = \int p(y_*|\mathbf{x}_*, \mathbf{x}, \mathbf{y}, \mathbf{f}) \cdot p(\mathbf{f}|\mathbf{y}, \mathbf{x}) d\mathbf{f}.$$

This is feasible but cumbersome. Alternatively, we can make use of the fact that the joint distribution of \mathbf{y} and y_* is known (cf. slides on noisy GP):

$$\begin{pmatrix} \mathbf{y} \\ y_* \end{pmatrix} \sim \mathcal{N}\left(\begin{pmatrix} \mathbf{m} \\ m_* \end{pmatrix}, \begin{pmatrix} \mathbf{K} + \sigma^2 \mathbf{I} & \mathbf{K}_* \\ \mathbf{K}_*^\top & K_{**} \end{pmatrix}\right),$$

with $m_* = m(x_*)$, $\mathbf{K}_* = k(x_*, \mathbf{x})$ and $K_{**} = k(x_*, x_*)$. The conditional distribution can then be derived using the rule of conditioning for Gaussian distributions:

$$y_*|\mathbf{x}_*, \mathbf{x}, \mathbf{y} \sim \mathcal{N}(m_* + \mathbf{K}_*^\top (\mathbf{K} + \sigma^2 \mathbf{I})^{-1} (\mathbf{y} - \mathbf{m}), K_{**} - \mathbf{K}_*^\top (\mathbf{K} + \sigma^2 \mathbf{I})^{-1} \mathbf{K}_*).$$

- (d) To implement a GP with squared exponential kernel and $\ell = 1$, we need the inverse of \mathbf{K} . \mathbf{x} being a vector implies that we have only one feature and thus the entries of our matrix \mathbf{K} are

$$\mathbf{K} = \begin{pmatrix} 1 & \exp(-0.5(x^{(1)} - x^{(2)})^2) \\ \exp(-0.5(x^{(2)} - x^{(1)})^2) & 1 \end{pmatrix}.$$

The inverse of \mathbf{K} is then given by

$$\frac{1}{1 - \exp(-(x^{(1)} - x^{(2)})^2)} \begin{pmatrix} 1 & -\exp(-0.5(x^{(1)} - x^{(2)})^2) \\ -\exp(-0.5(x^{(2)} - x^{(1)})^2) & 1 \end{pmatrix}.$$

If we have a noisy GP, we would have to add $\sigma^2 \mathbf{I}_2$ to \mathbf{K} with resulting inverse

$$\mathbf{K}_y^{-1} = \frac{1}{(1 + \sigma^2)^2 - \exp(-(x^{(1)} - x^{(2)})^2)} \begin{pmatrix} 1 + \sigma^2 & -\exp(-0.5(x^{(1)} - x^{(2)})^2) \\ -\exp(-0.5(x^{(2)} - x^{(1)})^2) & 1 + \sigma^2 \end{pmatrix}.$$

Assuming a zero mean GP, we can derive $\frac{\partial \mathbf{K}_y}{\partial \theta}$ with $\theta = \sigma^2$, which gives us the identity matrix. We can thus maximize the marginal likelihood (slide on *Gaussian Process Training*), by finding σ^2 that yields

$$\text{tr}(\mathbf{K}_y^{-1} \mathbf{y} \mathbf{y}^\top \mathbf{K}_y^{-1} - \mathbf{K}_y^{-1}) = 0.$$

This can be solved analytically (though quite tedious). We will use a root-finding function for this. For the posterior predictive distribution we can make use of the results from the previous exercise.
