

**Solution 1:**

See R code

**Solution 2:**

a)  $k = 3$

2 circles and 1 triangle, so our point is also a circle

b)  $k = 5$

3 circles and 3 triangles, we have to specify beforehand what to do in case of a tie

c)  $k = 7$

3 circles and 4 triangles, so our point is also a triangle

### Solution 3:

- a) When using the naive Bayes classifier, the features  $x := (x_{\text{Color}}, x_{\text{Form}}, x_{\text{Origin}})$  given the category  $y \in \{\text{yes}, \text{no}\}$  are assumed to be conditionally independent of each other, s.t.

$$p((x_{\text{Color}}, x_{\text{Form}}, x_{\text{Origin}})|y = k) = p(x_{\text{Color}}|y = k) \cdot p(x_{\text{Form}}|y = k) \cdot p(x_{\text{Origin}}|y = k).$$

For the posterior probabilities  $\pi_k(x)$  it holds that

$$\begin{aligned} \pi_k(x) &\propto \underbrace{\pi_k \cdot p(x_{\text{Color}}|y = k) \cdot p(x_{\text{Form}}|y = k) \cdot p(x_{\text{Origin}}|y = k)}_{=: \alpha_k(x)} \\ &\iff \exists c \in \mathbb{R} : \pi_k(x) = c \cdot \alpha_k(x), \end{aligned}$$

where  $\pi_k$  is the prior probability of class  $k$ . From this and since the posterior probabilities need to sum up to 1, it holds that

$$\begin{aligned} 1 &= c \cdot \alpha_{\text{yes}}(x) + c \cdot \alpha_{\text{no}}(x) \\ &\iff c = \frac{1}{\alpha_{\text{yes}}(x) + \alpha_{\text{no}}(x)}. \end{aligned}$$

This means in order to compute  $\pi_{\text{yes}}(x)$  the scores  $\alpha_{\text{yes}}(x)$  and  $\alpha_{\text{no}}(x)$  are needed.

Now we want to compute for a new fruit the posterior probability  $\hat{\pi}_{\text{yes}}(\text{(yellow, round, imported)})$ .

Note that we do not know the *true* prior probability and the *true* conditional densities. Here -since the target and the features are categorical- we can estimate them with the relative frequencies encountered in the data, s.t.

$$\begin{aligned} \hat{\alpha}_{\text{yes}}(x) &= \hat{\pi}_{\text{yes}} \cdot \hat{p}(\text{yellow}|y = \text{yes}) \cdot \hat{p}(\text{round}|y = \text{yes}) \cdot \hat{p}(\text{imported}|y = \text{yes}) \\ &= \hat{\mathbb{P}}(y = \text{yes}) \cdot \hat{\mathbb{P}}(x_{\text{Color}} = \text{yellow}|y = \text{yes}) \cdot \hat{\mathbb{P}}(x_{\text{Form}} = \text{round}|y = \text{yes}) \cdot \hat{\mathbb{P}}(x_{\text{Origin}} = \text{imported}|y = \text{yes}) \\ &= \frac{3}{8} \cdot \frac{1}{3} \cdot \frac{1}{3} \cdot 1 = \frac{1}{24} \approx 0.042, \\ \hat{\alpha}_{\text{no}}(x) &= \hat{\pi}_{\text{no}} \cdot \hat{p}(\text{yellow}|y = \text{no}) \cdot \hat{p}(\text{round}|y = \text{no}) \cdot \hat{p}(\text{imported}|y = \text{no}) \\ &= \hat{\mathbb{P}}(y = \text{no}) \cdot \hat{\mathbb{P}}(x_{\text{Color}} = \text{yellow}|y = \text{no}) \cdot \hat{\mathbb{P}}(x_{\text{Form}} = \text{round}|y = \text{no}) \cdot \hat{\mathbb{P}}(x_{\text{Origin}} = \text{imported}|y = \text{no}) \\ &= \frac{5}{8} \cdot \frac{2}{5} \cdot \frac{3}{5} \cdot \frac{2}{5} = \frac{3}{50} = 0.06. \end{aligned}$$

At this stage we can already see that the predicted label is "no", since  $\hat{\alpha}_{\text{no}}(x) = 0.06 > \frac{1}{24} = \hat{\alpha}_{\text{yes}}(x)$ . With this we can calculate the posterior probability

$$\hat{\pi}_{\text{yes}}(x) = \frac{\hat{\alpha}_{\text{yes}}(x)}{\hat{\alpha}_{\text{yes}}(x) + \hat{\alpha}_{\text{no}}(x)} \approx 0.41.$$

Corresponding R-Code:

```
df_banana <- data.frame(
  Color = as.factor(
    c("yellow", "yellow", "yellow", "brown", "brown", "green", "green", "red")),
  Form = as.factor(
    c("oblong", "round", "oblong", "oblong", "round", "round", "oblong", "round")),
  Origin = as.factor(
    c("imported", "domestic", "imported", "imported", "domestic", "imported",
      "domestic", "imported")),
  Banana = as.factor(c("yes", "no", "no", "yes", "no", "yes", "no", "no"))
)

new_fruit <- data.frame(Color = "yellow", Form = "round", Origin = "imported", Banana = NA)
df_banana <- rbind(df_banana, new_fruit)
```

nb_learner$predict(banana_task, row_ids = 9)

## <PredictionClassif> for 1 observations:
##   row_ids truth response   prob.no   prob.yes
##       9   <NA>       no 0.5901639 0.4098361

```

- b) For the distribution of a numerical feature given the the category we need to specify a probability distribution with continuous support. For example, for the information  $x_{\text{Length}}$  we could assume that  $p(x_{\text{Length}}|y = \text{yes}) \sim \mathcal{N}(\mu_{\text{yes}}, \sigma_{\text{yes}}^2)$  and  $p(x_{\text{Length}}|y = \text{no}) \sim \mathcal{N}(\mu_{\text{no}}, \sigma_{\text{no}}^2)$ . (To estimate these normal distributions one would need to estimate their parameters  $\mu_{\text{yes}}, \mu_{\text{no}}, \sigma_{\text{yes}}^2, \sigma_{\text{no}}^2$  on the data respectively)
