# Introduction to Machine Learning

# Pseudo-residuals and Gradient Descent

#### Learning goals

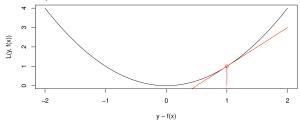

- Know the concept of pseudo-residuals
- Understand the relationship between pseudo-residuals and gradient descent

# **PSEUDO-RESIDUALS**

- In regression, residuals are defined as  $r := y f(\mathbf{x})$ .
- We further define pseudo-residuals as the negative first derivatives of loss functions w.r.t. f(x)

$$\tilde{r} := -\frac{\partial L(y, f(\mathbf{x}))}{\partial f(\mathbf{x})}.$$

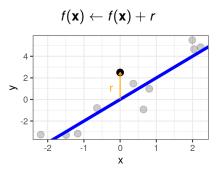

• Note that pseudo-residuals are actually functions of y and  $f(\mathbf{x})$  and depend on the loss function L.

# **BEST POINT-WISE UPDATE**

Assume we have fitted a model  $f(\mathbf{x})$  to data  $\mathcal{D}$ .

Assume we could update  $f(\mathbf{x})$  point-wise as we like. For a fixed  $\mathbf{x} \in \mathcal{X}$ , the best point-wise update is the direction of the residual  $r = y - f(\mathbf{x})$ 

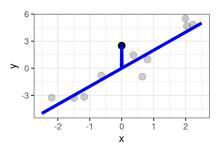

## **BEST POINT-WISE UPDATE**

Assume we have fitted a model  $f(\mathbf{x})$  to data  $\mathcal{D}$ .

Assume we could update  $f(\mathbf{x})$  point-wise as we like. For a fixed  $\mathbf{x} \in \mathcal{X}$ , the best point-wise update is the direction of the residual  $r = y - f(\mathbf{x})$ 

$$f(\mathbf{x}) \leftarrow f(\mathbf{x}) + r$$

The point-wise error at this specific  $\mathbf{x}$  becomes 0.

# APPROXIMATE BEST POINT-WISE UPDATE

When applying gradient descent to compute a point-wise update of  $f(\mathbf{x})$ , we would go a step into the direction of the negative gradient

$$f(\mathbf{x}) \leftarrow f(\mathbf{x}) - \frac{\partial L(y, f(\mathbf{x}))}{\partial f(\mathbf{x})}.$$

which is the direction of the pseudo-residual

$$f(\mathbf{x}) \leftarrow f(\mathbf{x}) + \tilde{r}$$

Iteratively stepping towards the direction of the pseudo-residuals is the underlying idea of gradient boosting, which is a learning algorithm that will be covered in a later chapter.

## GD IN ML AND PSEUDO-RESIDUALS

 In gradient descent, we try to move in the direction of the negative gradient in each step by updating the model accordingly

$$\boldsymbol{\theta}^{[t+1]} = \boldsymbol{\theta}^{[t]} - \alpha^{[t]} \cdot \nabla_{\boldsymbol{\theta}} \left. \mathcal{R}_{\mathsf{emp}}(\boldsymbol{\theta}) \right|_{\boldsymbol{\theta} = \boldsymbol{\theta}^{[t]}}$$

with step size  $\alpha^{[t]}$ .

• This can be seen as approximating the unexplained information (measured by the loss) through a model update.

# **GD IN ML AND PSEUDO-RESIDUALS**

 By using the chain rule we see that the pseudo-residuals are input to the update direction

$$\nabla_{\boldsymbol{\theta}} \mathcal{R}_{emp}(\boldsymbol{\theta}) = \sum_{i=1}^{n} \underbrace{\frac{\partial L\left(\boldsymbol{y}^{(i)}, f\right)}{\partial f}}_{=-\tilde{r}^{(i)}} \cdot \nabla_{\boldsymbol{\theta}} f\left(\mathbf{x}^{(i)} \mid \boldsymbol{\theta}\right)$$
$$= -\sum_{i=1}^{n} \tilde{r}^{(i)} \cdot \nabla_{\boldsymbol{\theta}} f\left(\mathbf{x}^{(i)} \mid \boldsymbol{\theta}\right).$$

 The unexplained information - the negative gradient - can be thought of as residuals, which is therefore also called pseudo-residuals.
